# Spectral learning for structured partially observable environments

Lucas Langer

Supervisors: Borja Balle, Doina Precup

August 18, 2015

#### Overview

- 1 Predictive state representation (PSR)
- 2 The Base System
- Experimental results
- 4 Learning the Base System

### Structure partially observable environments

#### **Structured Environments**

Goal: Predictions

Plan: Exploit structure

Example: Pacman

## PSR: The Timing Case

- Model environment with a Predictive state representation
- $\bullet$  For timing we have a one observation symbol  $\sigma$
- PSR defined by:  $<\alpha_0, \{A_{\sigma}\}, \alpha_{\infty}>$   $\alpha_0$ : Initial weighting on states 1xn
  - $A_{\sigma}$  Transition matrix  $n \times n$
  - $\alpha_{\infty}$ : Normalizer nx1
- PSRs compute probabilities of observations Notation:  $\sigma$ : one time unit,  $\sigma^k$ : k time units  $f(\sigma^k) = \alpha_0 * A_\sigma^k * \alpha_\infty$
- Examples of a PSRs: HMMs, POMDPs

#### Overview of Learning

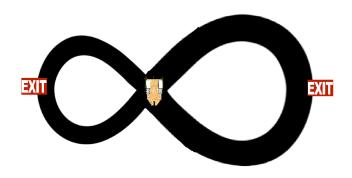

- Spectral algorithms can learn PSRs
- Flavour of learning algorithm:
  - Step 1: Represent data as a matrix
  - Step 2: Singular value decomposition
  - Step 3: Pick number of states for PSR
  - Step 4: Learn the PSR with matrix computations

## The Base System

- Idea: include  $\{A_a, A_{a^2}, A_{a^4}, ... A_{a^N}\}$  as additional operators
- Timing queries  $f(a^{11}) = \alpha_0 * A_{a^8} * A_{a^2} * A_{a^1} * \alpha_\infty$
- Motivation:
  - 1) Express transitions directly to avoid error build up
  - 2) Faster queries. Discussion:  $M^k * v$

#### Timing with the Base

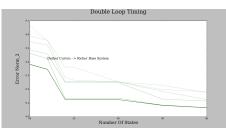

Agent goes through loops until leaving through an exit state. Exit states have transition probabilities of 0.4 and 0.6. Loop lengths are 64 and 16.

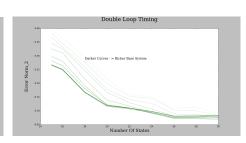

## Varying noise in loops

• Left Figure: No noise in durations

Right Figure: Noise in loops

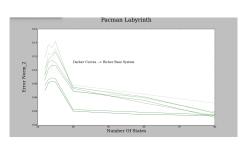

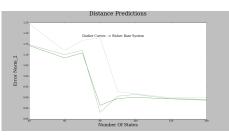

- Noise allows for smaller models
- $||f \hat{f}|| = \sqrt{\sum_{x \in observations} (f(x) f(x))^2}$

#### Pacman Labyrinth

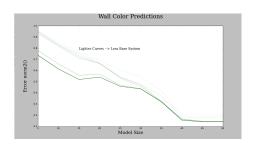

- Left figure: Timing predictions
- Right figure: Distance predictions

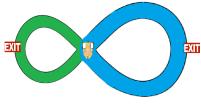

#### Wall Color Predictions

We paint the first loop green and the second loop blue.

#### Picking the Base System

- How do we pick transition operators?
  - Observations:  $\{"a^{30}":10, "a^{60}":5, "b^{18}":15\}$ Desired Base System:  $A_{a^{30}}, A_{b^{18}}, A_a, A_b$
- Substring properties: long, frequent, diverse
- Solution: iterative greedy heuristic

## Computing with the Base System

- Using the Base System well involves requires good **string partitions** Query string: "abcacb", Base System =  $\{A_{ab}, A_{bca}, A_{cb}, A_a, A_b\}$  Desired partition: "a—bca—cb""
- Goal: minimize matrices used
- Solution: dynamic programming

#### Conclusion and Future Work

- What's left for the Base System?
  - 1) Theoretical analysis
  - 2) Test heuristics on labyrinths
  - 3) Further optimize heuristics

## Questions? Comments?
